

	Original 2023	Reproduction 2026	what the reproduction found, and by which route
Population	●	●	The same four provinces and the same 1,023 cells of lattice.
Question	●	●	Unchanged: whether urban and paddy extent explain the methane field.
Hypothesis	●	●	Unchanged, and tested directly here rather than through a network.
Exp. design	!	≠	ERRATA 3.1, 3.3, 4.2. The training target was a colour-ramp JPEG, 81.5% of it white page; the backbone was randomly initialised and then frozen while described as pretrained. Rebuilt as baselines under two spatial cross-validation schemes. [dependent]
Experimenter	×	×	Neither study collected data. Both read published satellite products, so this stage belongs to third parties in both columns.
Data	●	≠	ERRATA 7.5, 7.3, 5.1. The 2018 urban extent reproduces from the same product to within 0.8%; the 2000 extent comes back 1.98 times high, because GAIA stores the year a pixel first turned impervious and a reprocessing re-dates it. Three products published since 2023 were used as well. [dependent and independent]
Analysis plan	!	≠	ERRATA 4.1. Section 3.3 describes a masked autoencoder, citing He et al. throughout; the implementation is supervised segmentation with nn.MSELoss and no masking anywhere. [dependent]
Analyst	●	●	The same person, which is the limit on what any of this can claim: a reproduction by its own author is not an independent check of the analyst.
Code	?	≠	ERRATA 3.5, 3.2. Every execution count in the committed notebook is null while 22 cells retain stored outputs, and the committed transforms would raise on the tensor the dataset class returns, so the stored losses cannot be tied to the code beside them. Rebuilt as tested modules under src/. [dependent]
Estimate	!	≠	ERRATA 1.1, 1.2, 6.5. Figure 4.7's three placements resolve to one PDF object with identical pixel hashes: it is the raw observation, not a prediction, and its caption states input years the body contradicts. No classification accuracy is reported anywhere. Held-out metrics are reported here instead. [dependent]
Claim	!	≠	ERRATA 2.1, 2.2, 7.1, 7.5. One stated multiplier is 3.84 against a stated sixfold and the 2010 total is out by 1; three neighbouring multipliers do recompute. The rice attribution is not supported, and the headline growth factor is reproduced by neither product. [dependent and independent]
● as the original had it ≠ present and different × not present ! not accurately represented ? cannot be tied to its stated source			

Rows are the eleven stages of the scientific process and columns are studies, which is the visual grammar Patil, Peng and Leek published for reproducibility and replicability (2019); the glyphs are its four states and one added here. ? is not one of the source's four: it marks something recorded that cannot be tied to what is said to have produced it, which is neither wrong nor absent, and ERRATA.md 3.5 is exactly that case. No colour carries meaning -- five states cannot be given five tones that separate by 0.15 in luminance, so the glyph carries the state and no pixel of this figure carries a hue. Which kind of reproduction is named per row after Desai, Abdelhamid and Padalkar (2025): dependent uses the original materials, independent rebuilds from the methodology. 4 of the 11 stages are unchanged in both columns, though one of those is the analyst, who is the same person, which is the limit on what any of this can claim. The 2023 numbers were consistent with the data the thesis had, and for the urban extents the data changed. Nothing here depicts the thesis's Figure 3.1: see ERRATA.md 4.1 and 3.3.
