

(a) GISA impervious, 30 m

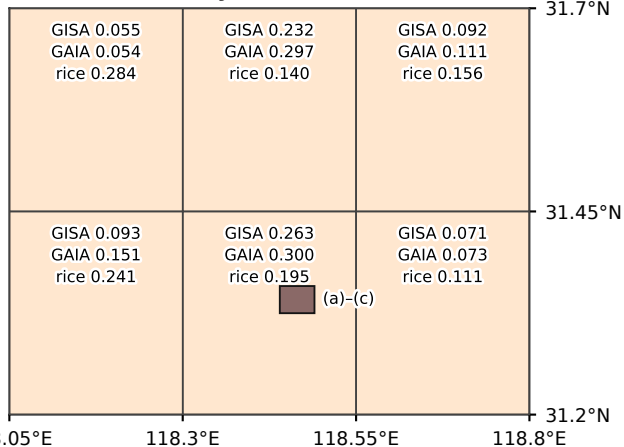

(b) GAIA impervious, 30 m

(c) NESDC rice, 10 m

(d) what the analysis reads: 0.25° cells

impervious surface rice, single season rice, double season neither, and looked at

GISA and GAIA are 30 m from Landsat; NESDC rice is 10 m from Sentinel-1 and Sentinel-2 by time-weighted dynamic time warping. The rice grid is three times finer and that buys the analysis nothing: both are averaged into the same 0.25° cell, about 24 by 28 km here.
